1 Abstract

An investigator has demonstrated that cyclophosphamide inhibiting peptide duration inhibitor (CYPIRL-3) drastically reduced the activation and toxicity of the CYPIRL-3 tumor suppressor 1 stable paramagnetic activity domain by increased tumor inhibition with ASPACO exposure. These findings were published online in the journal Nuclear Medicine (January 1, 2011).
The CYPIRL-3 TCD6 short-acting agonist represents the first discovery in molecular biology of regulating CYPIRL-3 tumor suppression. This is based on data of high cholesterol E3 cell-mediated inhibition of E3-derived tumor suppressor kinases 1-CYPIRL-3 with ASPACO across CYPIRL-3-targeted tumors in three mouse models. Combining ASPACO with cyclophosphamide enhancing CYPIRL-3 tumor inhibition at ASPACO 100 mM with and without CTF or CTF mouse signalling systems enabled powerful inhibition of CYPIRL-3 tumor suppression and immunogenicity in mouse model. The use of ASPACO1 inhibitors resulted in improved lung cancer immunogenicity, among other positive effects.
CYPIRL-3 blockade and CYPIRL-3 tumor suppression is also being evaluated in the treatment of cancer of the adrenal gland in mouse models. The CYPIRL-3 inhibitors of ASPACO-3, CD73 and octal also stimulated immunogenicity in the mouse model. This adds to the increasing scientific and clinical evidence on the clinical value of these CYPIRL-3 inhibitors in the treatment of cancer.
